The Broadcast Storm Problem

Self-Pruning

Simulation results

- Consist of wireless mobile hosts which form a temporary network
  - ◆ without the aid of established infrastructure (e. g. base stations)
  - ◆ without centralised administration (e. g. mobile switching centers)
  
- Every host in a MANET
  - ◆ can roam around freely
  - ◆ can only communicate with hosts which are currently in its transmission range
- ➔ Multi-hop scenario:  
Packets must be forwarded to their destination

# The Broadcast Storm Problem

Introduction

The Broadcast Storm Problem

● Overview

● Redundancy

● Contention

● Collision

● Observation

Self-Pruning

Simulation results

- Straightforward realisation of global broadcasting in a MANET
  - ↳ Simple Flooding:  
Every host retransmits a received broadcast message once.
  
- This leads to the so called *Broadcast Storm Problem* consisting of
  - ◆ Redundancy
  - ◆ Contention
  - ◆ Collision

# Redundancy (1)

Introduction

The Broadcast Storm Problem

- Overview
- **Redundancy**
- Contention
- Collision
- Observation

Self-Pruning

Simulation results

- **Problem:**  
 When a mobile host retransmits a broadcast message, all its neighbors might already have received this message.
- ➔ The bandwidth of the network gets reduced by unnecessary broadcasts.

(a)

(b)

# Redundancy (2)

- We are interested in the additional coverage of a node (grey shaded area)

- The additional coverage of *B*:

$$\pi r^2 - \text{INTC}(d)$$

where

$$\text{INTC}(d) = 4 \int_{d/2}^r \sqrt{r^2 - x^2} dx$$

- Expected additional coverage of a node:

$$\int_0^r \frac{2\pi x \cdot [\pi r^2 - \text{INTC}(x)]}{\pi r^2} dx \approx 0.41\pi r^2$$

# Redundancy (3)

- If a host received a broadcast message from more than one host, the expected additional coverage decreases.
- Expected additional coverage  $EAC(k)$  of a host after receiving a broadcast  $k$  times:

➔ Many rebroadcasts are superfluous in the case of simple flooding.

# Contention (1)

Introduction

The Broadcast Storm Problem

- Overview
- Redundancy
- **Contention**
- Collision
- Observation

Self-Pruning

Simulation results

- **Problem:**  
If  $n$  nearby hosts try to rebroadcast a message nearly the same time, they are likely to compete with each other.
- **Simple case of  $n = 2$ :**

- The probability of contention is  $\text{INTC}(x)/\pi r^2$

- For arbitrarily located  $B$ 's:

$$\int_0^r \frac{2\pi x \cdot \text{INTC}(x)/(\pi r^2)}{\pi r^2} dx \approx 59\%$$

# Contention (2)

Introduction

The Broadcast Storm Problem

- Overview
- Redundancy
- **Contention**
- Collision
- Observation

Self-Pruning

Simulation results

- The probability  $cf(n, k)$  of having  $k$  contention-free host among  $n$  receiving hosts:

➔ Contention is likely to occur, especially in dense networks.

# Collision

- **Problem:**  
Broadcast messages are rather sent simultaneously, such that collisions get more probable.
- **Reason:**  
CSMA/CA style communication
  - ◆ without RTS/CTS dialogues
  - ◆ without acknowledgement packets
- **Two problems:**
  - ◆ two hosts decide to transmit a message at around the same time
  - ◆ the hidden station problem

# Observation

Introduction

The Broadcast Storm Problem

- Overview
- Redundancy
- Contention
- Collision
- Observation

Self-Pruning

Simulation results

- Redundancy, Contention, Collision are serious problems.
- All problems have one cause in common:  
They increase with the number of hosts which unnecessarily rebroadcast a message.
- Solution:  
Inhibit some nodes in the MANET from rebroadcasting.  
↳ Select a *forward node set*

# Introduction to Self-Pruning (1)

Introduction

The Broadcast Storm Problem

Self-Pruning

● Introduction to Self-Pruning

● Coverage Condition I

● Coverage Condition II

● Comparison

● k-Hop Neighbor Set

Simulation results

- Self-Pruning: Every node decides on its own whether to forward a message or not.
- A forward node set has to form a *connected dominating set*.
  - ◆ A set  $A$  of nodes is called *dominating set* of a graph  $G$ , if every node is either in the set or has a neighbor in the set.
  - ◆ connected dominating set (CDS):

# Introduction to Self-Pruning (2)

Introduction

The Broadcast Storm Problem

Self-Pruning

● Introduction to Self-Pruning

● Coverage Condition I

● Coverage Condition II

● Comparison

● k-Hop Neighbor Set

Simulation results

- Ideal forward node set:  
*minimum connected dominating set (MCDS).*
- A *minimum connected dominating set (MCDS)* is a connected dominating set (CDS) with a minimal number of nodes.
- But:
  - ◆ MCDS problem is NP complete.
  - ◆ Global network information is needed for computation.
  - ➔ Define *coverage condition* which only results in a nearly optimal CDS but is suitable for computation.

# Coverage Condition I

Introduction

The Broadcast Storm Problem

Self-Pruning

● Introduction to Self-Pruning

● Coverage Condition I

● Coverage Condition II

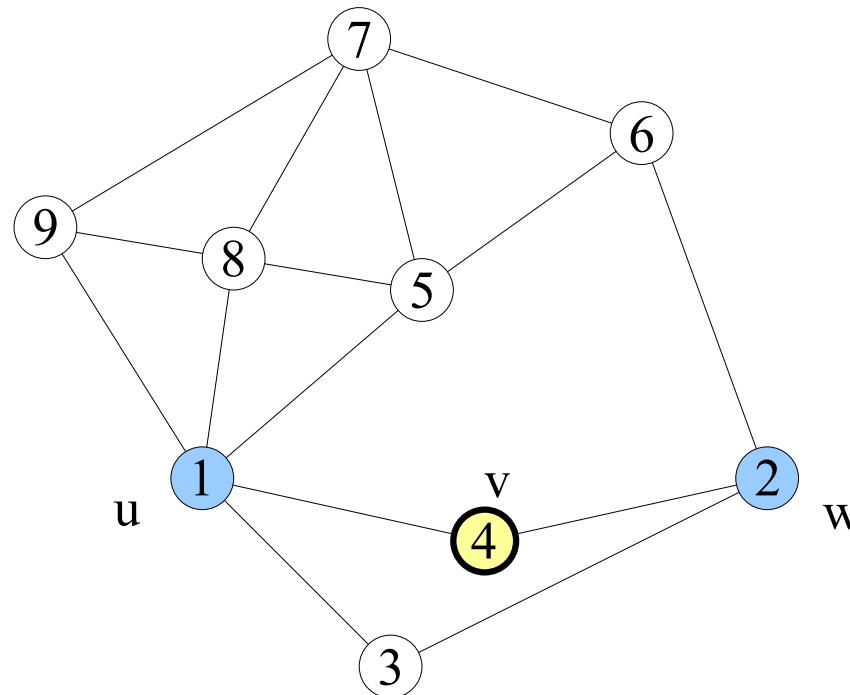

● Comparison

● k-Hop Neighbor Set

Simulation results

## ■ Coverage Condition I:

Node  $v$  has a non-forward node status if for any two neighbors  $u$  and  $w$ , a *replacement path* exists that connects  $u$  and  $w$  via several intermediate nodes (if any) with higher priority values than the priority value of  $v$ .

# Coverage Condition I

Introduction

The Broadcast Storm Problem

Self-Pruning

● Introduction to Self-Pruning

● Coverage Condition I

● Coverage Condition II

● Comparison

● k-Hop Neighbor Set

Simulation results

## ■ Disadvantage of Coverage Condition I:

- ◆ Every node has to check the condition for every pair of neighbors.
- ◆ There are  $\binom{\deg(v)}{2} \in O(\deg(v)^2)$  such pairs

➔ Overall computation complexity:  $O(n\Delta^2)$

$n$  – number of nodes

$\Delta$  – maximum vertex degree

# Coverage Condition II

## ■ Coverage Condition II:

Node  $v$  has a non-forward node status if it has a coverage set. In addition the coverage set belongs to a connected component of the subgraph induced from nodes with higher priority values than the priority value of  $v$ .

- A set  $C(v)$  is called a *coverage set* of  $v$  if the neighbor set of  $v$  can be covered by nodes in  $C(v)$ .

# Coverage Condition II

## ■ Computation:

- ◆ Decompose the graph into connected components  $V_1, V_2, \dots, V_l$  that only contain nodes with a higher priority than  $v$  via *depth-first search*. ( $O(n\Delta)$ )
- ◆ Compute for each  $V_i$  the set of covered neighbors  $N(V_i) := \bigcup_{w \in V_i} N(w)$  and check if there exists a  $V_i$  such that  $N(v) \subseteq N(V_i)$ . ( $O(n\Delta)$ )

➔ Overall computation complexity:  $O(n\Delta)$

# Coverage Condition I & II Comparison

Introduction

The Broadcast Storm Problem

Self-Pruning

● Introduction to Self-Pruning

● Coverage Condition I

● Coverage Condition II

● Comparison

● k-Hop Neighbor Set

Simulation results

- Coverage condition I is stronger than coverage condition II.
  - ◆ The existence of a *connected coverage set* for  $v$  implies the existence of a *replacement path* for any pair of  $v$ 's neighbors.
  - ◆ But generally the reverse situation does not hold:

- ➔ Coverage condition II has a lower computation complexity than coverage condition I but may result in larger forward node sets.

# k-Hop Neighbor Set $N_k(v)$

- For deciding whether to be a *forward node* or a *non-forward node*, a node can only use small neighborhood information:

↳ The k-hop neighbor set  $N_k(v)$

- $k = 2$ :

# Simulation Setup & Parameters

Introduction

The Broadcast Storm Problem

Self-Pruning

Simulation results

● Simulation Setup

● Neighborhood Information

● Coverage Condition

● Summary

- Because we are mainly interested in the size of the forward node set, we are assuming an ideal MAC layer without contention or collision.
  
- Simulation parameters:
  - ◆ number of hosts  $n$
  - ◆ average node degree  $d$  (density of the network)
  
- $n$  hosts placed randomly in a  $100 \times 100$  area.
  
- The transmission range  $r$  has been adjusted to produce  $\frac{nd}{2}$  links.

- **Summary**

What we have learned today:

- Basics of Mobile Ad Hoc Networks (MANETs)
- The Broadcast Storm Problem:
  - ◆ Redundancy
  - ◆ Contention
  - ◆ Collision
- How to avoid these problems:
  - ◆ Generic approach based on Self-Pruning
    - coverage conditions as approximation of a MCDS
      - ➔ Through simulation results we obtain a suitable configuration.

 Thank you for your attention.

# Applications

Introduction

The Broadcast Storm Problem

- scientific use
  - ◆ sensor networks
  - ◆ archaeological or ecological expeditions
- civilian use
  - ◆ disaster recovery
  - ◆ search and rescue
- military use
  - ◆ battlefield

# Why Broadcasting in a MANET?

Introduction

The Broadcast Storm Problem

Self-Pruning

Simulation results

Broadcasting in a MANET

- Broadcasts are common operations in MANETs
- Necessary for solving particular tasks in a MANET
  - ◆ sending alarm signals
  - ◆ paging particular hosts
  - ◆ possible last resort realisation of uni- and multicast messages in networks with a rapidly changing topology
  - ◆ many routing protocols use broadcasts to exchange routing information
- ➔ Due to the dynamic topology in MANETs, we expect broadcasts to occur more frequently.

# Maximal Replacement Path

**minimum node:** In a path  $P = (u, v_1, \dots, v_n, w)$  a *minimum node* is the intermediate node  $v_i$  with lowest priority value.

**max-min node:** Assume  $\{P_1, \dots, P_n\}$  is the set of all replacement paths for node  $v$  that connect  $u$  and  $w$ . Then a *max-min node* for  $(u, w, v)$  is the node with the highest priority value of all *minimum nodes* in  $P_1, \dots, P_n$ .

---

MAXMIN( $u, w, v$ )

---

- 1: **if**  $u$  and  $w$  are directly connected **then return**  $\emptyset$ .
  - 2: Find the max-min node  $x$  for  $(u, w, v)$ .
  - 3: **return** path (MAXMIN( $u, x, v$ ),  $x$ , MAXMIN( $x, w, v$ )).
- 

➔ Maximal replacement path:  $(u, \text{MAXMIN}(u, w, v), w)$

# Routing History

- Our approach does not consider the source of a broadcast.
- No need to transmit a broadcast to nodes where it comes from.
- ➔ Consider the *routing history* or *visited node set*  $D_h(v)$ , which contains the last  $h$  recent nodes.

# Priority Function

Introduction

The Broadcast Storm Problem

Self-Pruning

Simulation results

Priority Function

- Different priority function are possible:

- ◆ unique node id
- ◆ node degree
- ◆ neighborhood connectivity

$$= \frac{|\text{pairs of not directly connected neighbors}|}{|\text{pairs of any neighbors}|}$$
